2D Graphics Pipeline

Rasterization (Scan Conversion)

- Convert high-level geometry description to pixel colors in the frame buffer
- Example: given vertex x,y coordinates determine pixel colors to draw line
- Two ways to create an image:
 - Scan existing photograph
 - Procedurally compute values (rendering)

Rasterization

- A fundamental computer graphics function
- Determine the pixels' colors, illuminations, textures, etc.
- Implemented by graphics hardware
- Rasterization algorithms
 - Lines
 - Circles
 - Triangles
 - Polygons

Rasterization Operations

- Drawing lines on the screen
- Manipulating pixel maps (pixmap): copying, scaling, rotating, etc
- Compositing images, defining and modifying regions
- Drawing and filling polygons
 - Previously glBegin(GL_POLYGON), etc
- Aliasing and antialiasing methods

Line drawing algorithm

- Programmer specifies (x,y) values of end pixels
- Need algorithm to figure out which intermediate pixels are on line path
- Pixel (x,y) values constrained to integer values
- Actual computed intermediate line values may be floats
- Rounding may be required. E.g. computed point (10.48, 20.51) rounded to (10, 21)
- Rounded pixel value is off actual line path (jaggy!!)
- Sloped lines end up having jaggies
- Vertical, horizontal lines, no jaggies

Line Drawing Algorithm

Line: (3,2) -> (9,6)

Which intermediate pixels to turn on?

Line Drawing Algorithm

- Slope-intercept line equation
 - $y = mx + b$
 - Given two end points (x_0, y_0) , (x_1, y_1) , how to compute m and b ?

$$m = \frac{dy}{dx} = \frac{y_1 - y_0}{x_1 - x_0} \quad b = y_0 - m * x_0$$

Line Drawing Algorithm

- Numerical example of finding slope m :
- $(A_x, A_y) = (23, 41)$, $(B_x, B_y) = (125, 96)$

$$m = \frac{B_y - A_y}{B_x - A_x} = \frac{96 - 41}{125 - 23} = \frac{55}{102} = 0.5392$$

Digital Differential Analyzer (DDA): Line Drawing Algorithm

- Walk through the line, starting at (x_0, y_0)
- Constrain x , y increments to values in $[0, 1]$ range
- Case a: x is incrementing faster ($m < 1$)
 - Step in $x=1$ increments, compute and round y
- Case b: y is incrementing faster ($m > 1$)
 - Step in $y=1$ increments, compute and round x

DDA Line Drawing Algorithm (Case a: $m < 1$)

DDA Line Drawing Algorithm (Case b: $m > 1$)

```

x = x0          y = y0
Illuminate pixel (round(x), y)
y = y0 + 1      x = x0 + 1 * 1/m
Illuminate pixel (round(x), y)
y = y + 1       x = x + 1 /m
Illuminate pixel (round(x), y)
...
Until y == y1
    
```

DDA Line Drawing Algorithm Pseudocode

```

compute m;
if m < 1:
{
    float y = y0;          // initial value
    for(int x = x0; x <= x1; x++, y += m)
        setPixel(x, round(y));
}
else // m > 1
{
    float x = x0;          // initial value
    for(int y = y0; y <= y1; y++, x += 1/m)
        setPixel(round(x), y);
}

```

■ Note: `setPixel(x, y)` writes current color into pixel in column x and row y in frame buffer

Line Drawing Algorithm Drawbacks

- DDA is the simplest line drawing algorithm
 - Not very efficient
 - Round operation is expensive
- Optimized algorithms typically used.
 - Integer DDA
 - E.g. Bresenham algorithm (Hill, 10.4.1)
- Bresenham algorithm
 - Incremental algorithm: current value uses previous value
 - Integers only: avoid floating point arithmetic
 - Several versions of algorithm: we'll describe midpoint version of algorithm

Bresenham's Line-Drawing Algorithm

- Problem: Given endpoints (A_x, A_y) and (B_x, B_y) of a line, want to determine best sequence of intervening pixels
- First make two simplifying assumptions (remove later):
 - $(A_x < B_x)$ and
 - $(0 < m < 1)$
- Define
 - Width $W = B_x - A_x$
 - Height $H = B_y - A_y$

Bresenham's Line-Drawing Algorithm

- Based on assumptions:
 - W, H are +ve
 - $H < W$
- As x steps in +1 increments, y incr/decr by $\leq +1$
- y value sometimes stays same, sometimes increases by 1
- Midpoint algorithm determines which happens

Bresenham's Line-Drawing Algorithm

- Using similar triangles:

$$\frac{y - Ay}{x - Ax} = \frac{H}{W}$$

- $H(x - Ax) = W(y - Ay)$
- $-W(y - Ay) + H(x - Ax) = 0$
- Above is ideal equation of line through (Ax, Ay) and (Bx, By)
- Thus, any point (x, y) that lies on ideal line makes eqn = 0
- Doubling expression and giving it a name,

$$F(x, y) = -2W(y - Ay) + 2H(x - Ax)$$

Bresenham's Line-Drawing Algorithm

- So, $F(x, y) = -2W(y - Ay) + 2H(x - Ax)$
- Algorithm, If:
 - $F(x, y) < 0$, (x, y) above line
 - $F(x, y) > 0$, (x, y) below line
- Hint: $F(x, y) = 0$ is on line
- Increase y keeping x constant, $F(x, y)$ becomes more negative

Bresenham's Line-Drawing Algorithm

- Example: to find line segment between $(3, 7)$ and $(9, 11)$

$$\begin{aligned} F(x, y) &= -2W(y - Ay) + 2H(x - Ax) \\ &= (-12)(y - 7) + (8)(x - 3) \end{aligned}$$

- For points on line. E.g. $(7, 29/3)$, $F(x, y) = 0$
- A = $(4, 4)$ lies below line since $F = 44$
- B = $(5, 9)$ lies above line since $F = -8$

Bresenham's Line-Drawing Algorithm

What Pixels to turn on or off?

Consider pixel midpoint $M(M_x, M_y)$

$M = (x_0 + 1, Y_0 + \frac{1}{2})$

If $F(M_x, M_y) < 0$, M lies above line,
shade lower pixel

If $F(M_x, M_y) > 0$, M lies above line,
shade upper pixel (same y as before)

...

Bresenham's Line-Drawing Algorithm

- Algorithm: // loop till you get to ending x
 - Set pixel at (x, y) to desired color value
 - $x++$
 - if $F < 0$
 - $F = F + 2H$
 - else
 - $Y++$, $F = F - 2(W - H)$
- Recall: F is equation of line

Bresenham's Line-Drawing Algorithm

- Final words: we developed algorithm with restrictions
- Can add code to remove restrictions
 - To get the same line when $Ax > Bx$ (swap and draw)
 - Lines having slope greater than unity (interchange x with y)
 - Lines with negative slopes (step $x++$, decrement y not incr)
 - Horizontal and vertical lines (pretest $a.x = b.x$ and skip tests)
- Important: Read Hill 10.4.1
